

# SlicerRT

## radiation therapy extension for 3D Slicer

# DICOM aspects

Andras Lasso, Csaba Pinter

Laboratory for Percutaneous Surgery, Queen's University, Canada

# Commercial treatment planning systems (TPS)

# Existing research tools CERR, PLUNC, dicompyler, etc.

Expensive

Inconvenient

Limited feature set

Closed

Insufficient user and developer support

Open-source?

Cover only routine clinical procedures

Not extensible

Poor documentation

Not flexible

Well documented

Free

Large, non-modular code base

User-friendly

Extensible

Unstable

Stable

Flexible

Open-source

Platform-independent

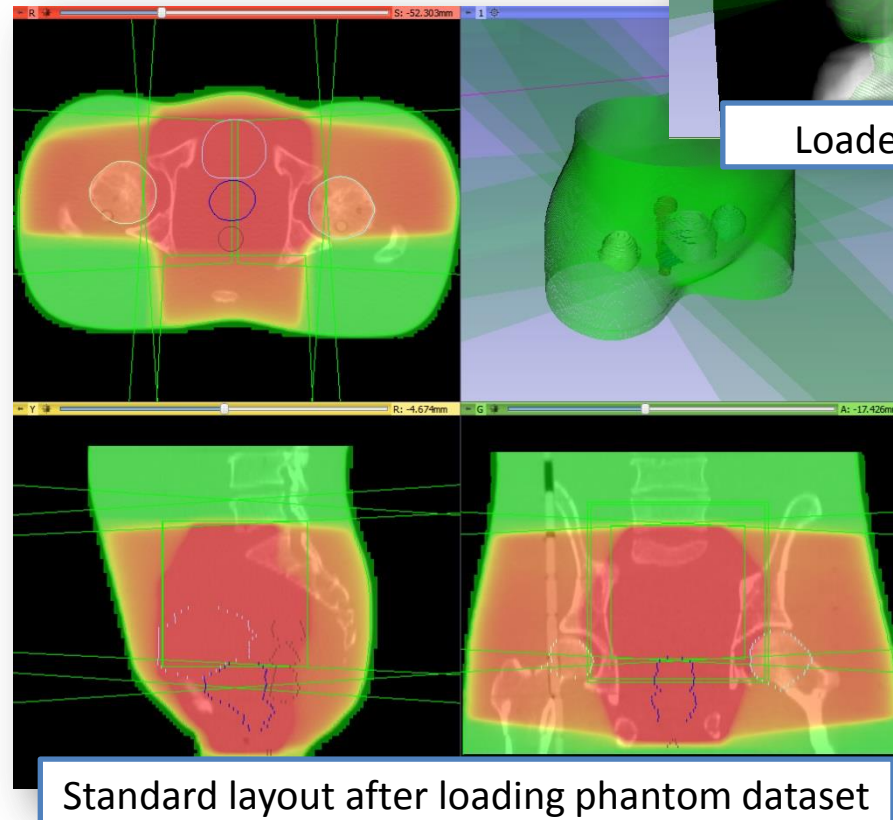

- “Hub” for RT data analysis and comparison
- Cover most common RT research workflows
- Funding secured till 2016

# SlicerRT

# DICOM-RT loading

- Using Slicer core's DICOM import plugin mechanism
- Supported data types:
  - RT structure sets
    - Contour nodes
    - Markup nodes
  - RT dose map
    - Volume node
  - RT image
    - Volume
  - + Planar image node
  - RT plan:
    - Plan node
    - Markup points

# Challenges: DICOM-RT loading

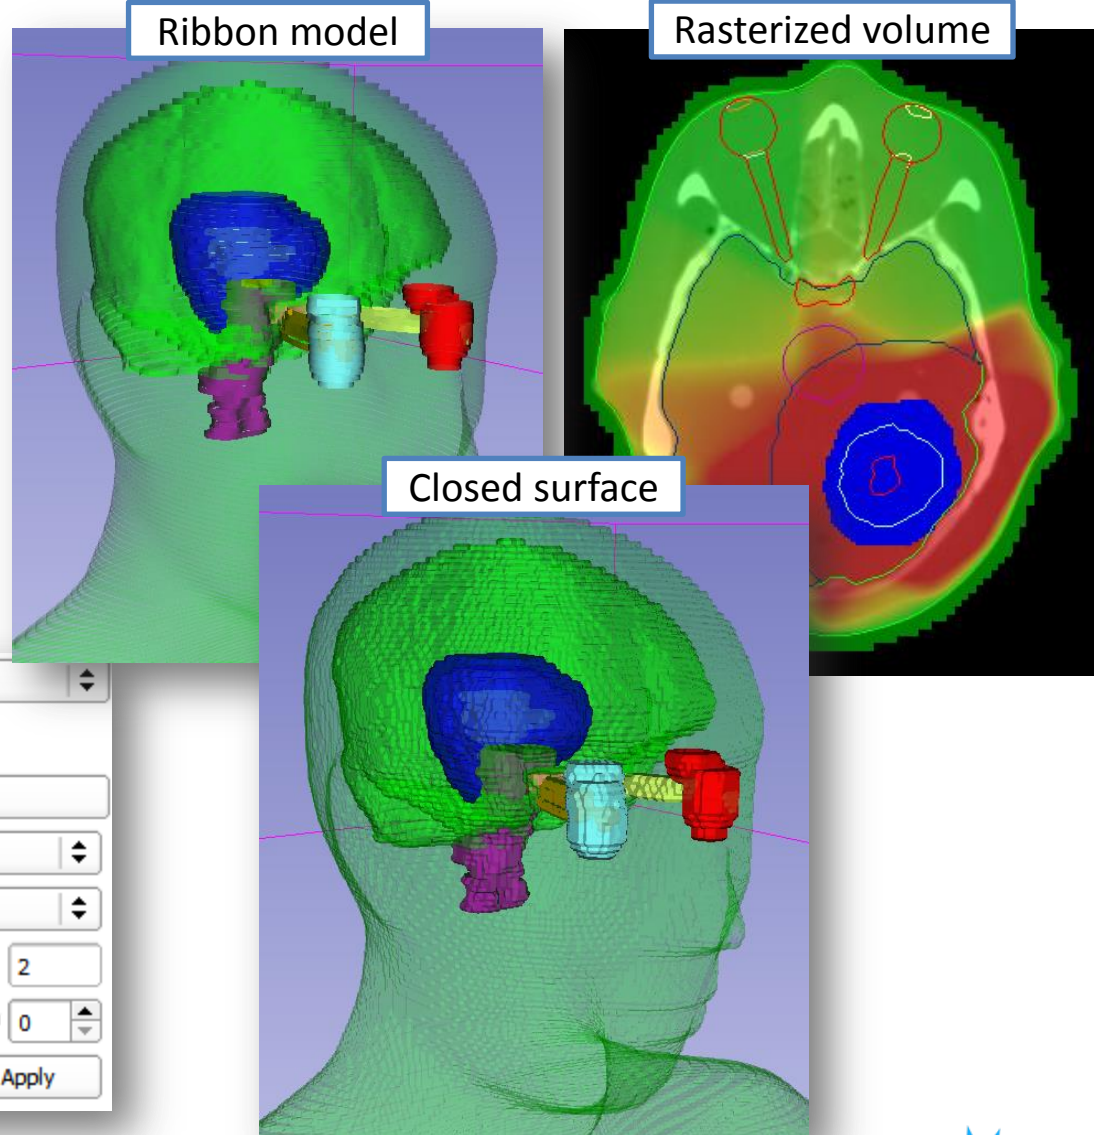

## 1. References between DICOM objects

- **Partial/random order loading** of a study and series. How to interpret data that depends on data that is not loaded?
  - Current solution: Store objects with DICOM UID in subject hierarchy. Check after each node adding if any new relationships can be added to the scene. Works so far for the RTIMAGE->RTPLAN, RTSTRUCT->CT, **could be generalized.**
- Resolving node references requires a lot of work (retrieve UID, find file, parse, search for needed data) – **Could higher-level objects be added to DCMTK?**

# Contour node

- Multiple representations
  - Ribbon model
  - Rasterized volume
  - Closed surface model
- Any representation is available: automatic conversion, caching
- Node selector widget

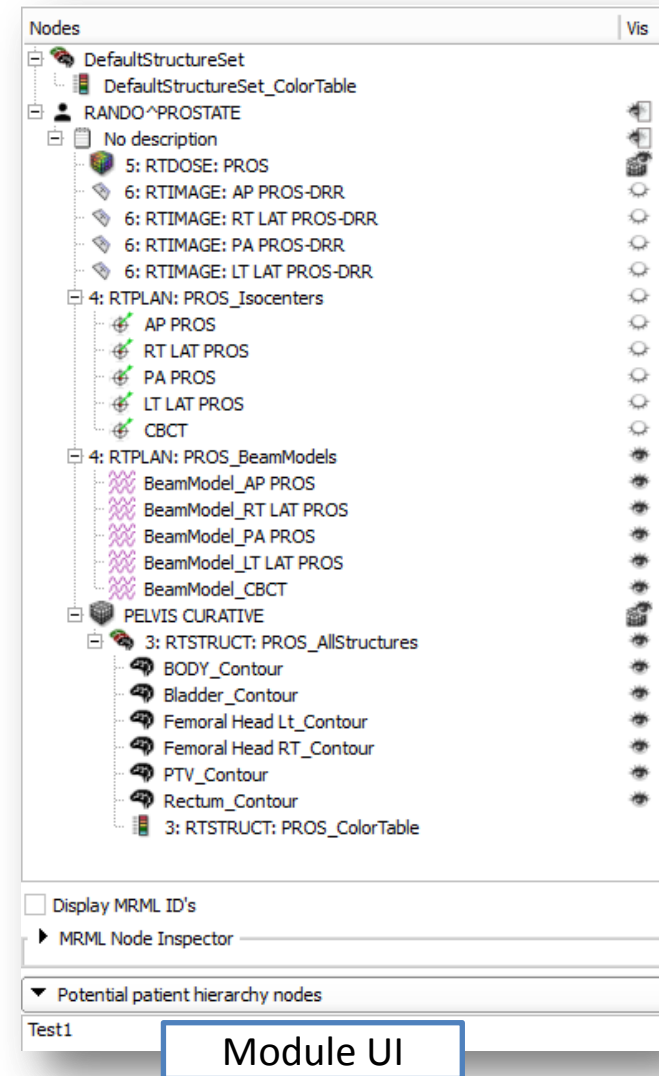

# Challenges: contours

1. Conversion from DCMTK to ITK/VTK objects
  - Should we have some common implementation? In ITK, VTK, CTK?
2. Loss-less ribbon (planar contours) to closed surface conversion
  - Algorithm development needed. Should we have some common implementation? In DCMTK, CTK, ITK, ...?
3. Co-existence with current segmentation management (that only uses labelmap volumes but allows multiple non-overlapping labels in a volume)
  - Contours should be integrated to the Slicer core. Editor, viewer, and CLI framework may require a lot of work.

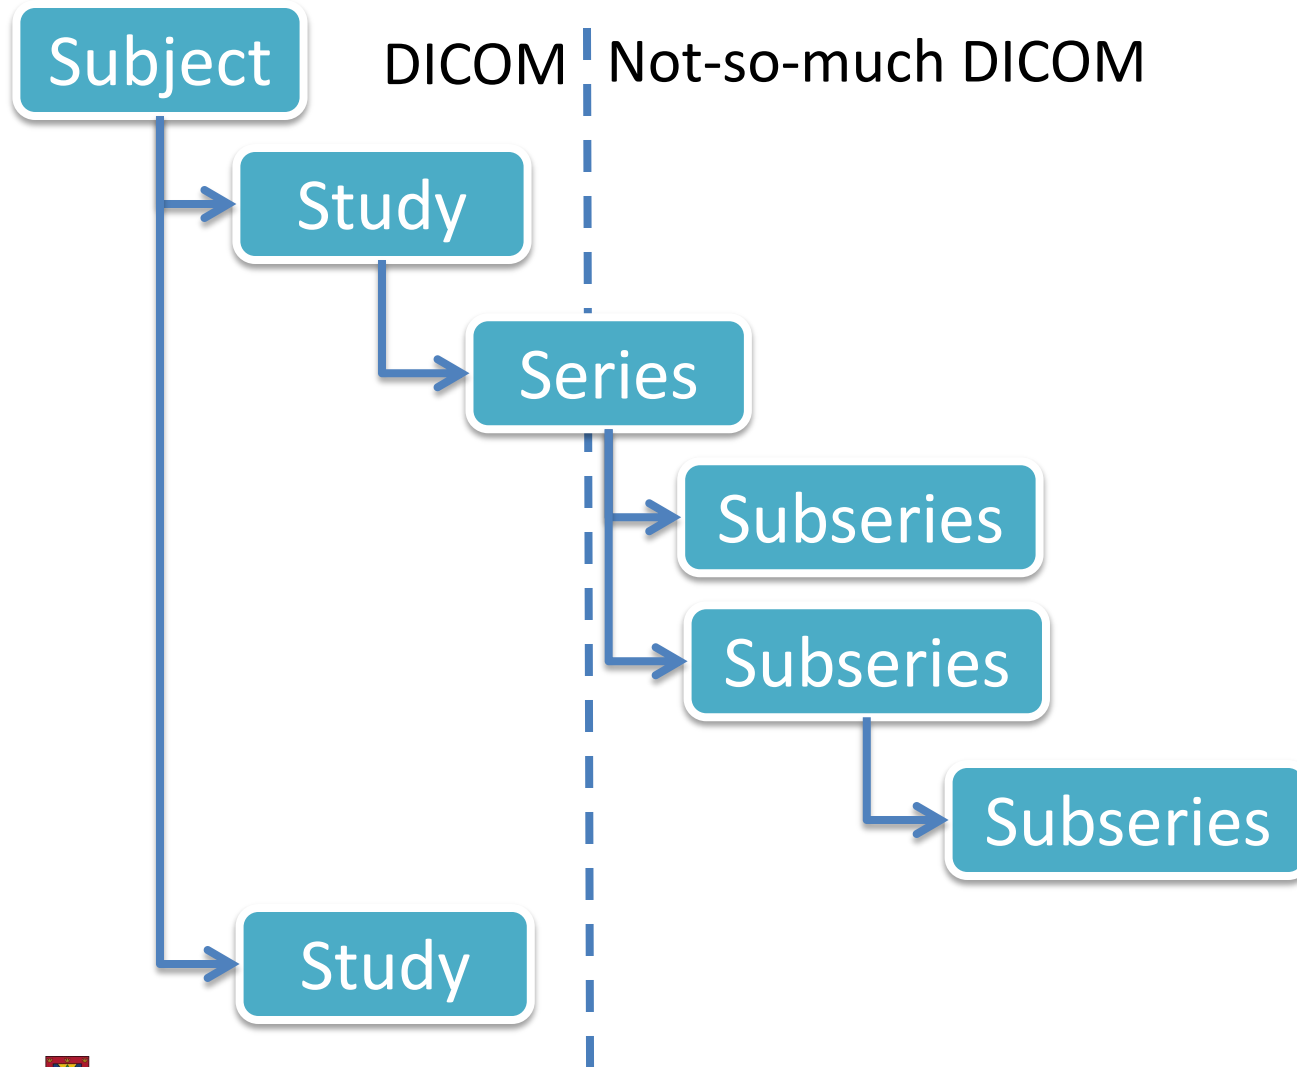

# Subject Hierarchy

- Group data for easier browsing
  - Show/hide branch; [future] show layout for whole study (e.g., PET/CT) and/or for a specific task (registration, dose accumulation, ...)
- Group data for easier processing
  - [future] Transformation of a whole study
- Define relationships
  - Bind MRML nodes to each other (e.g., isodose sets, color tables and dose volumes)
  - Bind MRML nodes to DICOM objects (e.g., allows accessing to all DICOM tags)
- Store metadata
  - In parent or associated hierarchy nodes
  - Data is modifiable (patient name etc. can be changed, useful for DICOM export)

# Subject hierarchy tree structure

# Subject hierarchy plugin mechanism

Outsources operations for specific node types. Virtual functions to override:

- Add node to the subject hierarchy
- Move node inside the subject hierarchy (reparent)
- [future] Create children node (get possible types, add a new child node)
- [future] Icon, tooltip

Example: contours have to deal with color tables and labelmap volume labels.

# Relationship between nodes

## 1. Subject hierarchy

### A. Parent/child/sibling relationship

- Good: **user can easily see & rearrange it**
- Bad: both related nodes have to be in the scene, only tree structure

### B. DICOM UID in associated hierarchy node

- Good: allows **accessing original DICOM data set** (with all DICOM tags), relationship can be defined for **nodes that are not in the scene yet**
- Bad: only available for DICOM data, and relationships defined in DICOM

Note: DICOM UID in node attribute is similar as in subject hierarchy, but less flexible – probably subject hierarchy will make it obsolete

## 2. MRML node reference

- Good: **can be used for observation** of node events (modifications, etc.)
- Bad: both related nodes have to be in the scene

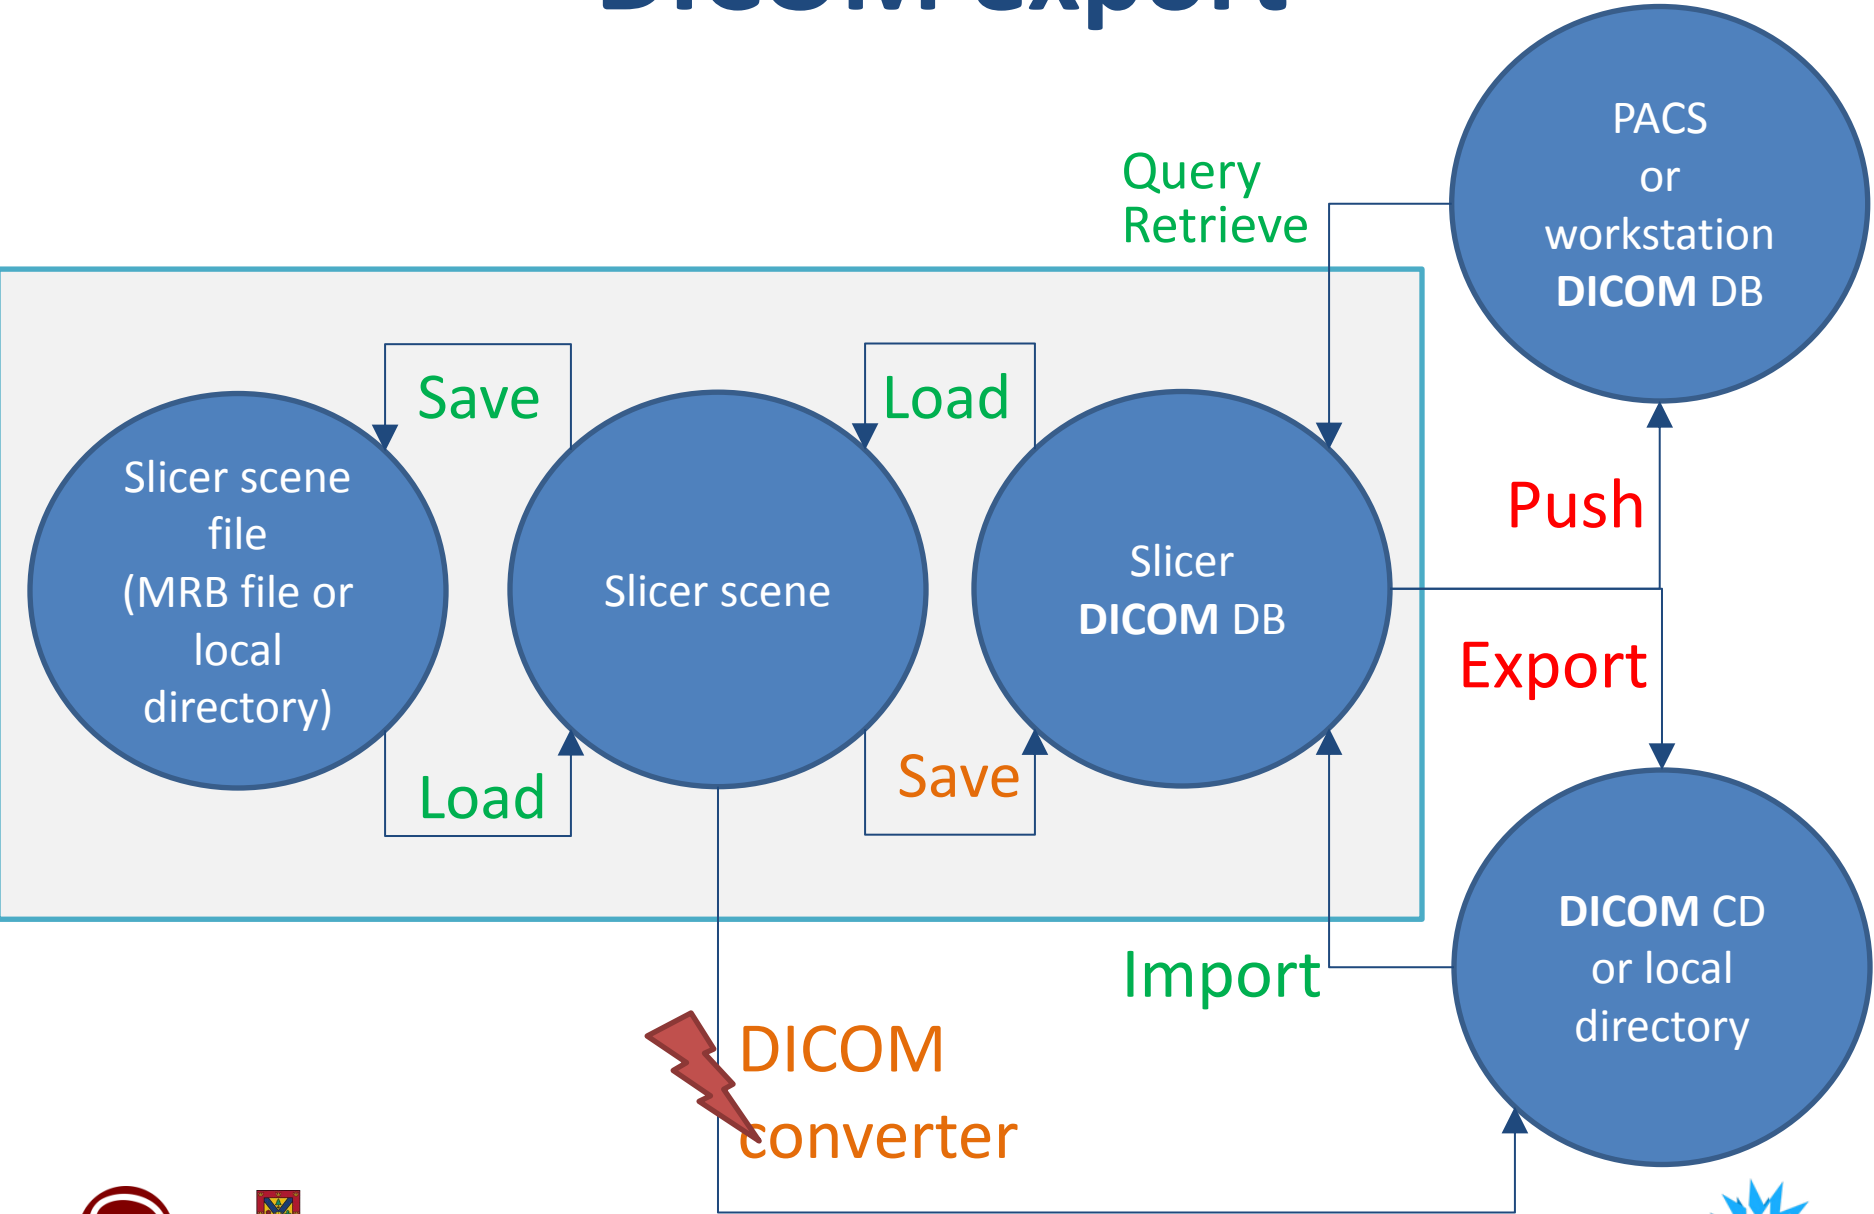

# Challenges: subject hierarchy

1. CLI compatibility
  - Processing results should be placed into the subject hierarchy automatically
  - Also save some node attributes?
2. Data is attached to a patient in the subject hierarchy. Should it appear in the DICOM browser?
3. Subject hierarchy plugins should be added
  - for structured reports, registration objects, etc.
4. Should be part of the Slicer core
5. How to identify patients? (how UIDs are usually composed?)

# DICOM export

# Challenges: DICOM export

1. Too many data repositories – can be simplified?
  - Can we unify the DICOM loading/saving and other file loading/saving in the same browser? Store both DICOM and non-DICOM data in the Slicer database?
  - Workflow? Where to put in the GUI?
2. No plugin architecture exists yet for DICOM exporters

# Multidimensional data

- Store/retrieve/analyze data along multiple dimensions
  - Dimensions: Time, modality, imaging parameters...
- Multidimensional array is decomposed and stored in a tree structure
- Design options:
  - Store all the data in the scene: save/load, references, access to nodes are solved; problems: potential performance issues, hidden nodes are not well supported
  - Store data in sub-scenes (similar to scene views): better performance (scene doesn't get too big), nodes are not all available in the scene

# Subject Hierarchy

## Series types

- Volume  
Associated to `vtkMRMLScalarVolumeNode` types
  - Generic (CT, MR, ...): modality CT, MR
  - Dose: modality RTDOSE
  - RT image: modality RTIMAGE
- Structure set (contour hierarchy): modality RTSTRUCT  
`vtkMRMLDisplayableHierarchyNode` type, associated to nothing. Its children subseries are contours (`vtkMRMLContourNode`) and a color table
  - *DicomRtImport.ContourHierarchy* attribute
- Plan: modality RTPLAN  
`vtkMRMLAnnotationHierarchyNode` type, associated to nothing. Its children subseries are beams and source, isocenter fiducials
